Sporadic cases of Ebola virus disease in Europe are unavoidable. This is due to travel between Europe and affected countries.

However, the risk of **spread** of Ebola in Europe is avoidable and extremely low. European countries are among the best prepared in the world to respond to viral haemorrhagic fever (VHF) including Ebola.

There is a risk of accidental contamination for people exposed to Ebola patients: this risk can be and must be mitigated with strict infection control measures. Health care workers are on the frontline of the Ebola fight and they are those most at risk of infection. They need to be protected and supported by all means.

All countries have protocols and procedures that must be implemented when a case is suspected and it is important that these are followed diligently. WHO is, as always, ready to provide help and support where requested.
