

The outbreak of Middle East Respiratory Syndrome, or MERS, in the Republic of Korea continues to evolve. WHO is in close contact with the country's government and Ministry of Health, and is receiving information as soon as facts are confirmed.

The quality of reporting has allowed almost real-time insight into the dynamics of the outbreak. Aggressive contact tracing and testing for infection may help explain the rapid expansion of the outbreak. Human-to-human transmission has been documented. At this stage, WHO has no evidence of sustained transmission in the community.

Korea's first, or "index", case was confirmed on 20 May and notified to WHO the same day. The case occurred in a 68-year-old Korean national with a recent history of travel to four countries in the Middle East. The case was asymptomatic during his return flight to Korea on 4 May.

He developed symptoms on 11 May and subsequently sought care at two out-patient clinics and two hospitals, creating multiple opportunities for exposure among health care workers and other patients.

As the index case provided no history of potential exposure to the virus, MERS was not suspected and the patient was not treated in isolation. Efforts are under way to gather more information about exposures during the patient's travels in the Middle East.

Expansion of the outbreak

The outbreak is the largest reported outside the Kingdom of Saudi Arabia, where the disease first emerged in April 2012 and the vast majority of cases have occurred.

To date, contact tracing has identified a total of 25 laboratory-confirmed cases, including the index case and among health care workers caring for him, patients who were being cared for at the same clinics or hospitals, and family members and visitors.

Some of these additional cases were in the same room as the index case; others were on the same ward. Though data are preliminary, exposure times that led to infection may have been as short as five minutes to a few hours.

To date, two of these cases have been fatal.

Given the number of clinics and hospitals that cared for the index case, further cases can be expected.

Middle East Respiratory Syndrome (MERS) in the Republic of Korea

Écrit par WHO

Jeudi, 04 Juin 2015 17:42 -

On 26 May, one of the confirmed cases with an exposure history in Korea travelled, against medical advice, to Guangdong, China, via Hong Kong. He was symptomatic at the time of travel. On 29 May, China informed WHO that the patient, who was isolated at a Huizhou hospital, tested positive for the MERS coronavirus.

The occurrence of such a large outbreak outside the Middle East is a new development, as is exportation of the disease to a third country. The Ministry of Health has further reported that two recently confirmed cases represent a third generation of transmission – from the index case, to someone exposed to that case, to a third person with no direct exposure to the index case.

Consistent application of adequate measures for infection prevention and control has halted other large clusters of cases associated with health care facilities. WHO recommends that droplet precautions be added to standard measures when providing care to patients with symptoms of acute respiratory infections.

WHO does not advise special screening at points of entry nor does it currently recommend the application of any travel or trade restrictions.

MERS is a newly emerging disease that remains poorly understood. Much about the behaviour of the virus remains shrouded in scientific uncertainty, though evidence is mounting that dromedary camels can transmit the virus to humans through close contact.

WHO is confident that investigations under way in Korea, including the sequencing of viruses and sharing of the findings, will contribute to further scientific understanding of this disease.
